2. Introduction

The purpose of this document is to outline the procedural steps required to enter various Reverse Proton Studies modes. When we are stacking, the P1, P2 and AP1 lines are all configured for 120 GeV protons. When switching to Reverse Protons, we must stop stacking and setup the lines for 8 GeV protons. The 8 GeV protons then are sent down the AP3 line, where they are injected onto the injection orbit in the Accumulator. From there, we can extract the 8 GeV beam down the D/A line to the Debuncher. We can either circulate the reverse protons in the Debuncher or extract them up the AP2 line. We will outline how to configure the Antiproton Source in a number of different Reverse Proton studies configurations.

First, we will outline how to establish Reverse Protons circulating in the Debuncher from either dedicated TLG events or “one shots.” We will then outline how to extract the Reverse Protons from the Debuncher down the AP2 line either from circulating Debuncher beam or using partial turn Debuncher extraction. We will then cover how to setup for up D/A line studies. Lastly, we will cover how to return Pbar to normal stacking.

Reverse Proton Setup Procedures

Many of the steps needed to enter and exit these study modes are consolidated into two Pbar sequencers called the Pbar Sequencer and Pbar Annex Sequencer. Other steps require manual intervention. We will assume that we are starting with the Pbar source configured in stacking mode.

3. Setup for Reverse Protons

From stacking mode, our first goal is to configure the Antiproton Source for reverse protons. To do so, we will run the first three aggregates in the Pbar Annex sequencer, followed by the first portion of the Pbar Sequencer “Reverse Protons to Debuncher” aggregate.

We will start by entering the Pbar Sequencer, which can be found on Acnet page P64.

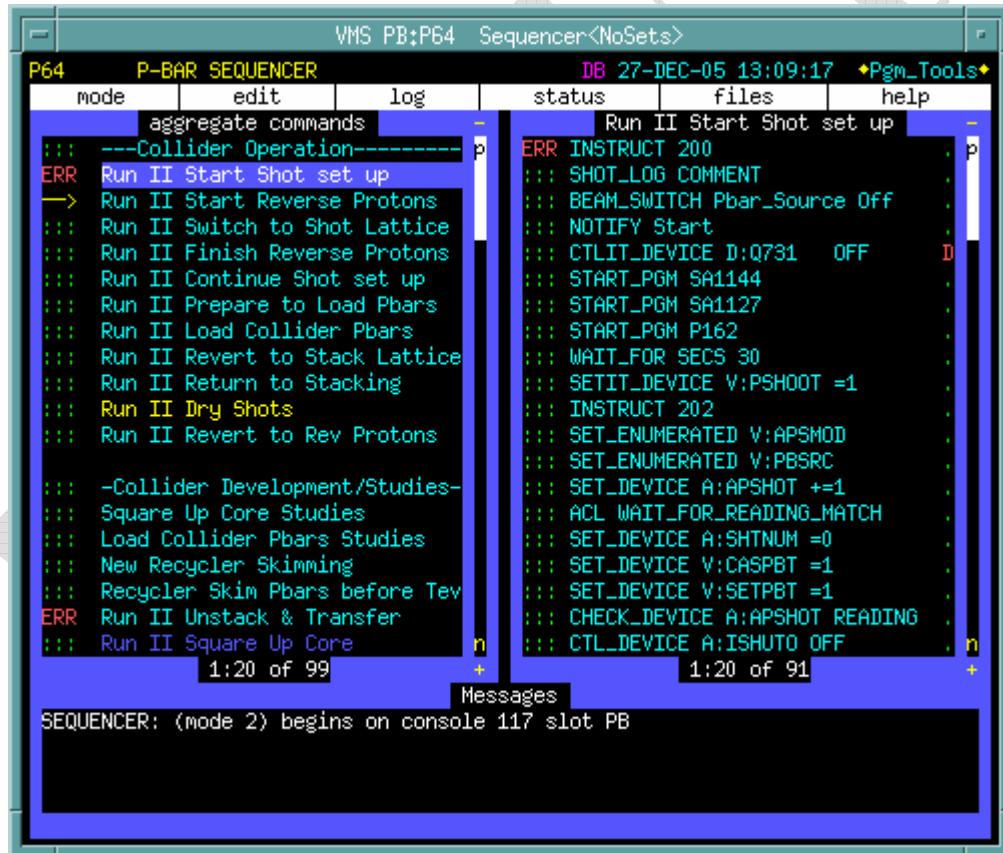

Figure 3-1: The Pbar Sequencer.

After entering the Pbar Sequencer, click on the menu bar item “mode” in the upper left corner of the screen. Select the Pbar Annex (Mode 17) from the selection menu.

Reverse Proton Setup Procedures

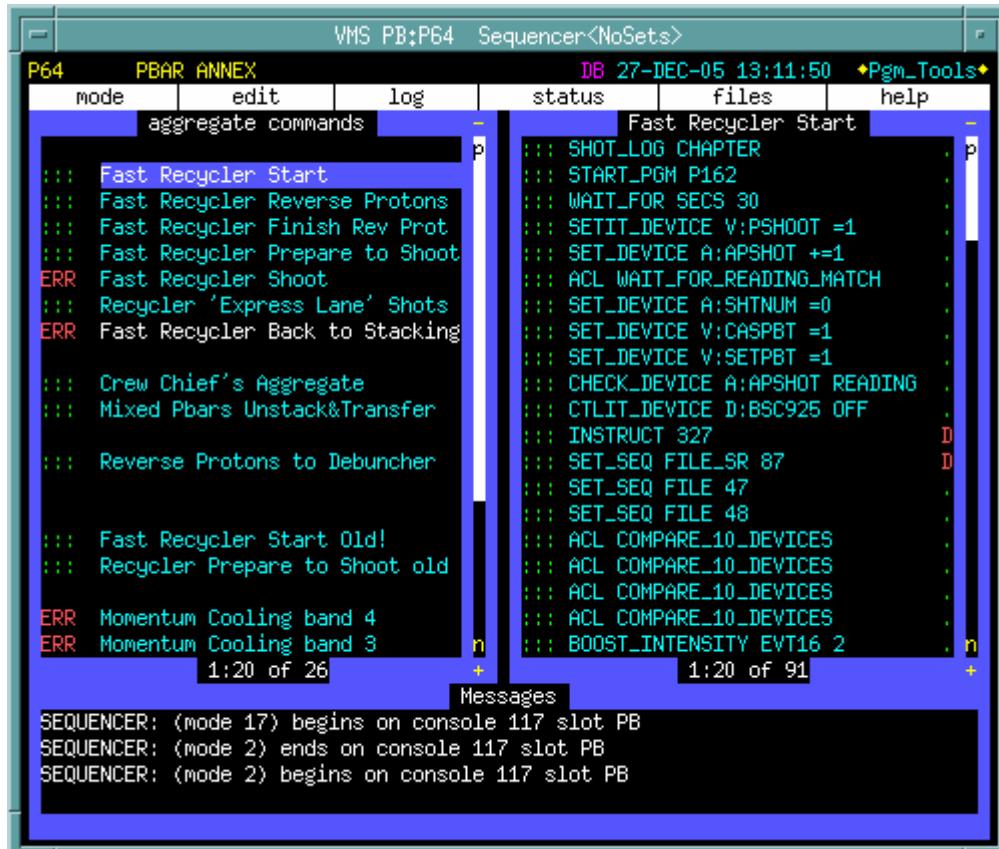

Figure 3-2: The Pbar Annex Sequencer.

We will now run the first three aggregates in the Pbar Annex Sequencer. The same three aggregates are used in the initial stages of the Accumulator to Recycler transfers so there are some commands that may not be necessary for our Reverse Proton studies. We will attempt to point these out as we go along.

a. **Pbar Annex Sequencer: Fast Recycler Start**

Click on “Fast Recycler Start” in the left column of the sequencer. The right column now shows the commands in this sequencer. To start this aggregate, click on the green “:::” on the first command in the sequence. We will now step through each command in the sequencer.

::: SHOT_LOG CHAPTER

This command starts a new shot log chapter in the Recycler shot scrapbook at <http://www-bd.fnal.gov/cgi-mach/machlog.pl?nb=rscrap03&load=no>. Since we are not completing a Recycler shot, we can actually skip this command and start the aggregate at the next command.

Reverse Proton Setup Procedures

::: START_PGM P162

Starts the Accumulator BPM TBT Page P162 (keeper is Keith Gollwitzer). This page, as shown below, checks the status of the Accumulator BPM houses and issues resets to any house that is not online. This allows plenty of time for the BPM houses to reboot before they are need in the beam line tune-up. Upon completion, this application self terminates and the window will close on its own.

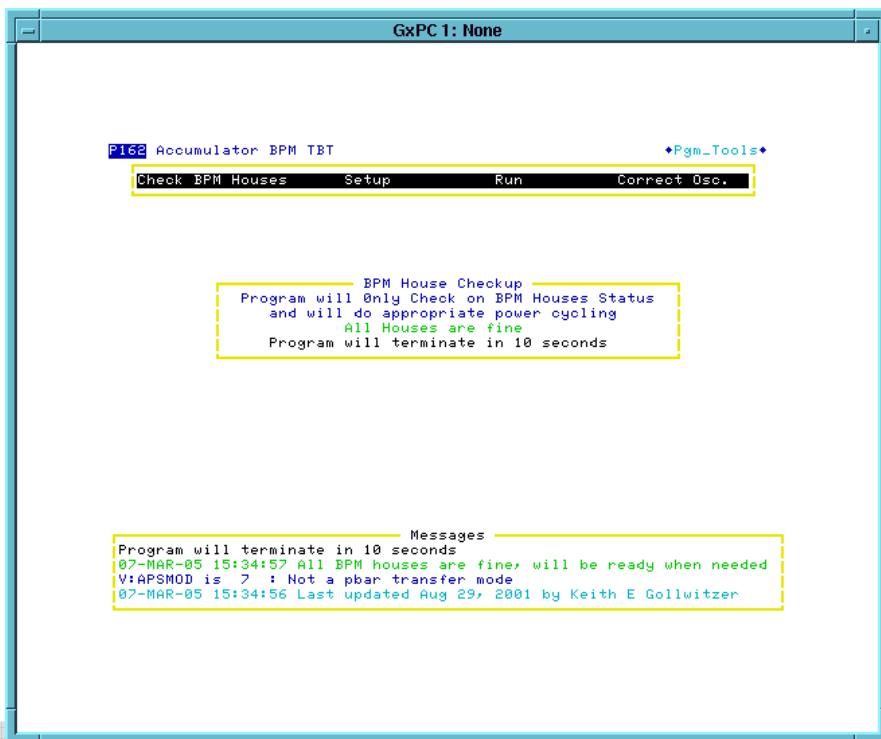

Figure 3-3:

::: WAIT_FOR_SECS 30

This command waits 30 seconds for the previous command to complete.

::: SETIT_DEVICE V:PSHOOT =1

Sets the state parameter V:PSHOOT to 1, then pauses long enough to verify that the setting was completed successfully.

Devices that start with V: are called state parameters. State parameters define the operational state of a device or accelerator, allow the sequencers to be more automated, and prevent the different sequencers from getting out of sequence with each other. Often one sequencer waits at a certain spot until another sequencer changes a state parameter.

Reverse Proton Setup Procedures

V:PSHOOT is a state parameter for the Pbar transfer state. V:PSHOOT state 1 means “not ready for transfer.” Later in this aggregate, V:PSHOOT is set to 4 (“Ready for Main Injector Tune up”). The **Main Injector Shot Transfer Line Tuneup** aggregate waits for PSHOOT to be set to 4 (“Ready for Main Injector Tune up”) before starting its beam line tune-up.

::: SET_DEVICE A:APSHOT +=1

Increments A:APSHOT by 1. This is the Pbar transfer series number, which is incremented before and after any Pbar transfer from the Accumulator to the Tevatron or Accumulator to the Recycler. This command is not necessary for Reverse Proton Studies.

::: ACL_WAIT_FOR_READING_MATCH

A Runs an Accelerator Command Language (ACL) script called WAIT_FOR_READING_MATCH that waits for "SDA Shot/Store #" (A:FILE) to read the same value as the Pbar transfer series number (A:APSHOT). More information on ACL scripts can be found at http://adcon.fnal.gov/userb/www/controls/clib/intro_acl.html.

::: SET_DEVICE A:SHTNUM =0

Sets the “Pbar transfer series Shot #” parameter (A:SHTNUM) to zero. Later on A:SHTNUM is incremented by one for every Pbar transfer. This is not used during Reverse Proton Studies.
